Linear Difference Equations and Asset Pricing

Jesse Perla University of British Columbia

December 21, 2016, Draft Version: 373

1 Uniqueness of Solutions?

Continuing with our linear asset pricing example,

1.1 Solution:

How can we solve a difference equation?

Example: $y_t = \bar{y}$

$$P_t = \bar{y} + \beta P_{t+1} \tag{1}$$

A Guess: $P_t = \bar{P}$, independent of t. Plug in equation (1):

$$\bar{P} = \bar{y} + \beta \bar{P} \tag{2}$$

$$\Rightarrow \bar{P} = \frac{\bar{y}}{1-\beta}$$
, consistent with $P = \sum_{t=0}^{\infty} \beta^t y_t$ (3)

Role of $|\beta| < 1$:

- $\bullet\,$ Keep from "exploding": stability
- Will have equivalent condition for more complicated difference equations

1.2 Rational Bubbles

Let $y_t = \bar{y}$ for all t.

Fundamental value:

$$P_t = \sum_{j=0}^{\infty} \beta^j \bar{y} \tag{4}$$

$$=\frac{\bar{y}}{1-\beta}, \text{ (unique)} \tag{5}$$

Remember that this solves the recursive problems as well:

$$\frac{\bar{y}}{1-\beta} = \bar{y} + \beta \left(\frac{\bar{y}}{1-\beta}\right) \Rightarrow \text{true!} \tag{6}$$

Is $P_t = \frac{\bar{y}}{1-\beta}$ the unique solution to $P_t = \bar{y} + \beta P_{t+1}$? **No!** Like the undetermined coefficient in differential equations.

Example:

$$P_t = \underbrace{\frac{\bar{y}}{1-\beta}}_{\text{fundamental}} + \underbrace{c\beta^{-t}}_{\text{bubble term}} \text{ for any } c$$

$$(7)$$

Check: $P_t = \bar{y} + \beta P_{t+1}$

$$\frac{\bar{y}}{1-\beta} + c\beta^{-t} = \bar{y} + \beta \left[\frac{\bar{y}}{1-\beta} + c\beta^{-(t+1)} \right]$$
(8)

$$= \bar{y} + \left(\frac{\beta}{1-\beta}\right)\bar{y} + c\beta^{-t} \tag{9}$$

$$=\frac{\bar{y}}{1-\beta} + c\beta^{-t} \tag{10}$$

So it fulfills the difference equation for any c, t, etc. Rational as every agent in the economy would agree on the price, no-one needs to be tricked or making a pricing mistake, and there is no arbitrage. An example of a self-fulfilling equilibrium.

1.2.1 Size of the "Rational Bubble"

$$\underbrace{P_0 - P_{fund}}_{\text{difference from fundamental}} = \frac{\bar{y}}{1 - \beta} - \frac{\bar{y}}{1 - \beta} + c\beta^0 = c \tag{11}$$

Expectations:

- Prices rise because they are expected to rise.
- Self fulfilling. Will depend on coordination of expectations.
- Is Fiat money a bubble?

2 Extending our Asset Pricing Model

We will generalize our results to include systems of equations, with dynamics.

2.1 Recall: Properties

- Dividend stream y_t
- Discount factor β
- Present discounted value = price : $P = \sum_{t=0}^{\infty} \beta^t y_t, \text{ and if } y_t = \bar{y}, \ P = \bar{y}(1-\beta)^{-1}$
- How to model the evolution of y_t ?
 - Will use systems of linear difference equations.
- Example: dividends are a linear function of evolving aggregate and idiosyncratic variables

Recall: Recursive Formulation $P_t = y_t + \beta P_{t+1}$

2.2 Applying to Dynamics

- \bullet Let x_t be a n dimensional vector of states.
- Let A, G be matrices.
- \bullet Stack first order difference equations, giving another $canonical\ form$:

$$x_{t+1} = A \cdot x_t,$$
 (A is $n \times n$ matrix, x is $n \times 1$ vector) (12)

$$y_t = G \cdot x_t,$$
 (G is $1 \times n$ vector, y_t is a scalar, i.e. 1×1) (13)

- 'A' gives evolution of the state, given x_0
- 'G' gives observation of the state "Finding the state is an art"

Example:

• Asset payoff follows difference equation (not first order!):

$$y_{t+1} = \rho_1 y_t + \rho_2 y_{t-1} \tag{14}$$

• What is the value of this asset at time t?

State

Guess:
$$x_t \equiv \begin{bmatrix} y_t \\ y_{t-1} \end{bmatrix}$$
, 2 × 1 vector.

What is the difference equation for x_t ?

$$\underbrace{\begin{bmatrix} y_{t+1} \\ y_t \end{bmatrix}}_{x_{t+1}} = \underbrace{\begin{bmatrix} \rho_1 & \rho_2 \\ 1 & 0 \end{bmatrix}}_{A} \underbrace{\begin{bmatrix} y_t \\ y_{t-1} \end{bmatrix}}_{x_t} \tag{15}$$

and observation:

$$y_t = \underbrace{\begin{bmatrix} 1 & 0 \end{bmatrix}}_{G} \underbrace{\begin{bmatrix} y_t \\ y_{t-1} \end{bmatrix}}_{g} \tag{16}$$

Therefore, the set of difference equations in our *canonical form* are:

$$x_{t+1} = Ax_t \tag{17}$$

$$y_t = Gx_t (18)$$

Price is:

$$P_t = \sum_{j=0}^{\infty} \beta^j y_{t+j} \tag{19}$$

$$=\sum_{j=0}^{\infty} \beta^j G \cdot x_{t+j} \tag{20}$$

If $x_{t+1} = A \cdot x_t$, then $x_{t+2} = A \cdot (Ax_t) = A^2 x_t$, and $x_{t+j} = A^j x_t$

$$\Rightarrow P_t = \sum_{j=0}^{\infty} \beta^j G \cdot A^j \cdot x_t \tag{21}$$

$$= G \cdot \left[\sum_{j=0}^{\infty} (\beta A)^j \right] x_t \tag{22}$$

Remember that if λ is scalar: $\sum_{j=0}^{\infty} (\beta \lambda)^j = (1-\beta \lambda)^{-1} = \frac{1}{1-\beta \lambda}$. With matrices and inverses, this is similar: $\sum_{j=0}^{\infty} \beta^j A^j = (I-\beta A)^{-1}$, where the matrices' dimensions are: $A: n \times n$, $I = n \times n$ identity, $(I-\beta A)^{-1}: n \times n$

$$P_t = G(I - \beta A)^{-1} x_t \quad (*: very important memorize)$$
 (23)

- Asset pricing formula for first-order linear difference equations.
- Summary of sizes:
 - $P_t: 1 \times 1$ scalar
 - $G: 1 \times n$ vector
 - $A: n \times n$ matrix
 - $I: n \times n$ identity matrix
 - $\beta: 1 \times 1$ scalar
 - $x_t : n \times 1$ state vector

2.3 Stability

- Recall in the example with $x_t = \lambda^t$ that $|\beta \lambda| < 1$ for the series to converge.
- For matrix equations, need a similar condition where eigenvalues of βA are all < 1, or $\max |\operatorname{eig}(A)| < \frac{1}{\beta}$
- Can use software to check the eigenvalues.

Appendix A Connection to Differential Equations

Difference equations are just differential equations in discrete time.

- Let y(t) be the flow dividends, a function of t.
- \bullet Let r be the instantaneous interest rate.

- Let the length of a period be Δ , and take the limit as it goes to 0.
- Dividends over Δ period $\approx \Delta y(t) \equiv y_t(\Delta)$
- Discounting over Δ period $\approx 1 \Delta r \equiv \beta(\Delta)$

The difference equation is: $P_t = y_t + \beta P_{t+1}$.

Using the above \Rightarrow Let function p(t) be the price of asset:

$$p(t) = \Delta \cdot y(t) + (1 - \Delta r) \cdot p(t + \Delta) \tag{A.1}$$

Rearrange:

$$\Delta r \cdot p(t + \Delta) = \Delta \cdot y(t) + p(t + \Delta) - p(t) \tag{A.2}$$

$$\Rightarrow rp(t+\Delta) = y(t) + \frac{p(t+\Delta) - p(t)}{\Delta}$$
(A.3)

Take limit as $\Delta \to 0$, i.e. discrete \to continuous t

$$\partial p(t) = \frac{p(t+\Delta) - p(t)}{\Delta}$$
, definition of a derivative (A.4)

where $\partial p(t) = \frac{d}{dt}p(t)$

$$\Rightarrow \underbrace{rp(t)}_{\text{opportunity cost}} = \underbrace{y(t)}_{\text{flow}} + \underbrace{\partial p(t)}_{\text{capital}}$$
of buying a unit of the asset.

(A.5)

- Consider this pricing equation and arbitrage:

What if $rp(t) < y(t) + \partial p(t)$ instead of being an equation?

Appendix B Popping Bubbles

- In our discrete time model, keep $y_t = \bar{y}$ deterministic for simplicity:
 - Let the bubble term have a chance of popping each period.
 - Therefore, prices are a random variable.
 - Linear asset pricing if random:

$$P_t = y_t + \beta \mathbb{E}_t [P_{t+1}]$$
 (Expected value of P_{t+1} given information at t) (B.1)

B.1 Bubble Evolution

Let
$$C_{t+1} = \begin{cases} \frac{1}{\lambda} C_t & \text{with prob. } \lambda \in (0,1) \\ 0 & \text{with prob. } 1 - \lambda \end{cases}$$
 (B.2)

i.e., C_t multiplied by $\frac{1}{\lambda}$ each time until bubble breaks. Then $C_t=0$ $\forall t$

Note:

$$\mathbb{E}_t \left[C_{t+1} \right] = \lambda \left(\frac{1}{\lambda} C_t \right) + (1 - \lambda) \cdot 0 = C_t \tag{B.3}$$

If $\mathbb{E}_{t}[y_{t+1}] = y_{t}$, then this term is called a *martingale*.

B.2 Price Level

We can check that for any C_0 :

$$P_{t} = \begin{cases} \frac{\bar{y}}{1-\beta} + (\beta\lambda)^{-t} \cdot C_{0} & \text{if bubble hasn't popped} \\ \frac{\bar{y}}{1-\beta} & \text{after bubble pops} \end{cases}$$
(B.4)

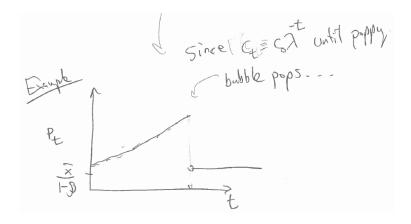

Figure 1: Graphical representation of the price level when the bubble pops
